Certain commercial entities, equipment, or materials may be identified in this document in order to describe an experimental procedure or concept adequately. Such identification is not intended to imply recommendation or endorsement by the National Institute of Standards and Technology, nor is it intended to imply that the entities, materials, or equipment are necessarily the best available for the purpose.

The authors would like to thank the Department of Homeland Security's Office of Biometric Identity Management (OBIM), and Prof. Jeremy Dawson and the staff of the West Virginia University Biometrics Collection Lab for their support and making twins data available to NIST.

The authors are grateful to staff in the NIST Biometrics Research Laboratory for infrastructure supporting rapid evaluation of algorithms. Thank you to Dr. Jim Matey, Joyce Yang, and Karen Marshall for the comments of the paper.

Abstract

This report documents the ability of face recognition algorithms to correctly distinguish face images of identical and fraternal twins. The algorithms were submitted to the ongoing one-to-one verification track of the Face Recognition Vendor Test (FRVT) executed by the National Institute of Standards and Technology (NIST)

Executive Summary

Overview

This report documents the ability of face recognition algorithms to correctly distinguish face images of identical and fraternal twins. The algorithms were submitted to the ongoing one-to-one verification track of the Face Recognition Vendor Test (FRVT) executed by the National Institute of Standards and Technology (NIST).

Motivation

Face recognition is increasingly used in public and private sector applications for authentication of a person's identity, for authorization of transactions, and for logical and physical access control. These uses have been supported by the massive improvements in accuracy documented in NIST FRVT evaluation [3] over the last decade. Since the COVID-19 pandemic, these gains include the ability of some algorithms [4] to recognize individuals wearing protective face masks. However, despite these gains, face recognition algorithms continue [14] to give false matches when comparing face images of twins, and this report documents results on the most recent algorithms. This is a problem, because in 2020 approximately 3% of babies born in the US were twins and multiple births [13]. The numbers of twins are rising due to increased age of having babies and use of infertility treatments [11]; The twin birth rate has risen over 70% since 1980 [7].

What we did

We applied one-to-one face comparison algorithms to face images of twins and to face images of the general population. The algorithms were submitted to the FRVT by corporate research and development laboratories, and universities. These algorithms were prototypes and not available for commercial use. Their performance is detailed in FRVT [3]. We used two sets of face images. The first dataset was from West Virginia University collected at Twins Days Festivals [6] [8] from 2010 to 2018. These images have good compliance with image capture standards. The second set consists of images collected by the U.S. Government in operational travel and immigration processes. The images are of lower quality given constraints on capture duration and environment, and are only in partial compliance with image capture standards. This data consist of all same-sex twins but unknown twin types. Together we used a total of 5 938 images from 698 pairs of twins. Both datasets were accompanied by sex, birth year and matching twin identifiers for the photographed individuals. The Twins Days data also included the twin types, identical or fraternal, noting that fraternal twins can be of different sex. We quantified false match rates - statements of

how well face recognition algorithms are able to differentiate twins. We report results by age groups and twin types.

What we found

All of the algorithms submitted to the FRVT verification track are unable to distinguish between identical twins: They give false match on identical twins pairs (see Tables 1 and 14-27). Likewise, most algorithms give false matches for same-sex fraternal twins - this becomes modestly less likely for older people. For different-sex fraternal twins, most algorithms do not give false matches. These results show that identical twins and same-sex fraternal twins give outcomes that are inconsistent with the intended or expected behaviour from a face recognition algorithm.

			TWINS DAY				
	ALGORITHM		Mugshot	TEMPLATES	IDENTICAL	FRATERNAL	FRATERNAL
				TEMILATES	TWINS	SAME-SEX	DIFFER-SEX
	NAME	SUBMISSION DATE	FNMR	FTE	FMR	FMR	FMR
1	sensetime-006	2021-12-28	0.0021	0.000	0.996	0.812	0.029
2	sensetime-005	2021-05-24	0.0021	0.000	0.996	0.790	0.029
3	paravision-010	2022-02-02	0.0021	0.000	0.995	0.783	0.044
4	psl-009	2021-12-08	0.0021	0.000	0.995	0.848	0.162
5	idemia-008	2021-07-07	0.0022	0.000	0.996	0.783	0.059

Table 1. This table presents results for five algorithms with good performance on FRVT 1:1 mugshot data with FNMR @ FMR = 0.0001. They all give high False Match Rate (FMR) on identical twin comparisons. However, identical twins FMR is not 1 because there are identical twins comparisons have scores below the threshold, because the images of the twins do not look alike, have different face shapes, and wearing hats. (Threshold is set to give FMR = 0.0001 when executing same-sex non-mated comparisons in a general mugshot population.)

Technical Summary

Score distributions

False matches are the result of high similarity scores produced by algorithms when comparing images of different people, in our case, twins. Figure 1 shows the distributions of scores for two accurate and representative algorithms.

The highest scores arise from comparison of images of the same person taken on the same day - these are labeled "mated twins". The next highest scores come from a general mugshot population adopted here as a control. These are labeled "mated mugshot". Scores from comparing images of two identical twins are similarly high and are labeled "non-mated identical twins". Almost as high are scores from "non-mated fraternal samesex twins". All of these are above threshold, which we set to give FMR = 0.0001 on a set of non-mated mugshot pairs. It is impractical to elevate the threshold to suppress false matches from twins without simultaneously elevating false non-match rates to operationally useless levels.

Age effects

When examining twins in different age groups, both datasets show declines in similarity scores for non-mated twins in the older age groups. There are four age groups in the Twins Days dataset, age 0-19, age 20-39, age 40-59, and age 60-up. The results show algorithms

have lower similarity scores for twins in the oldest age group than the youngest age group when comparing images of fraternal same-sex twins and identical twins. Immigration-related datasets have all same sex twins and three age groups, age 0-19, age 20-39, and age 40-59. The distributions of similarity scores in the age 0-19 are closer to the mated twins scores, while the similarity scores in the age 40-59 are lower and away from the mated twins score distribution. Even though both datasets show a decline in similarity scores in the older age groups, scores are still above the thresholds where the algorithm would still consider the non-mated twins comparison a match. Therefore, the algorithms are not able to differentiate same-sex fraternal twins and identical twins as different people.

Longitudinal effects

As face recognition algorithms performance improves, the ability to differentiate same-sex twins shows no improvement. Algorithms with good performance on mugshot data show no improved or declined performance when comparing fraternal same-sex twins and identical twins in the Twins Days data. See Tables 14-27

Anomalous algorithms

In the main results tables in the report, there are a handful of algorithms that give low false match rates for identical twins. These algorithms, also fail to match mated twin pairs also i.e. the algorithms are very inaccurate.

Implications and future work

Identical twins have extremely similar facial appearance, because they share the same genes[2]. Fraternal same-sex twins share half of the genes and may look different from each other[1]. In the NIST face recognition verification test, algorithms have high false matches and cannot distinguish identical and fraternal same-sex twins as different people. The operational consequences of this are application dependent.

Future mitigation of this problem may involve accessing facial information that is not phenotypic and determined by genetics. Facial landmarks are distinctive and useful, but usually there only few of these features on the face and sometimes they cannot be observed in low resolution of the images. High resolution images may provide more details about the facial skins, perhaps match by certain facial skin areas, pores pattern, facial skin patterns[12]. We suggest this because a patented algorithm from 2004, US Patent: US7369685B2, was known to be able to correctly differentiate twins by extracting features from skin texture

visible in higher resolution images. An ISO-compliant frontal portrait with a minimum of 120 pixels between the eyes was considered suitable for skin texture based analysis - that format is achieved using a 480 x 640 (VGA) pixel image.

Going forward we expect to use Twins Days images which have interocular distances (as defined in ISO/IEC 39794-5:2019) of 500 pixels and above, and conformance to the ANSI-NIST level 50 specifications [8][5] (see Table 2) to challenge industry to demonstrate low false match in twins. In FRVT, we note that many convolutional neural networks are configured to consume lower resolution inputs to optimize for speed, and the images are either resized to a lower resolution or are heavily compressed which would remove the higher resolution features.

Dama				INTEROC	CULAR D	ISTANCE			
DATA	1%	5%	10%	25%	50%	75%	90%	95%	99%
Twins Day Images	598.1	634.3	670.6	760.6	804.9	843.7	881.6	905.5	954.8
Immigration-related Images	24.0	27.1	29.5	34.0	42.0	59.4	76.4	119.7	151.7

Table 2. Quantile of the mean interocular distance calculated from 5 algorithms (cubox-002, psl-008, idemia-008, clearviewai-000, paravision-008) reported eye coordinates for the images during template creation.

1. Introduction

Face recognition algorithms are used around the world in a diverse range of biometric applications [10] to authenticate users, for identity de-duplication in databases, and more. These algorithms are rapidly improving in performance and accuracy, and take on new challenges at the same time, such as authenticating users while wearing face masks. However, distinguishing twins remains a problem for face recognition, because face recognition algorithms continue to mis-identify twins as the same person.

This report contains the twins accuracy measurement for 1:1 verification algorithms. We tested algorithms that were submitted to FRVT 1:1 Ongoing [3]. At this time, we do not have any information regarding whether or not any of the algorithms were designed to distinguish between twins.

The FRVT evaluation is an ongoing test that remains open to new participation. Comments and suggestions should be directed to frvt@nist.gov.

2. Image Datasets

There are three different types of comparisons - Mated Twins which compares images of the same person, Non-Mated Twins which compares images of twin siblings, and Non-Mated Non-Twins which compares images of different people in the same dataset who are not the twin siblings. In the Twins Days dataset, images used in mated and non-mated twins comparisons are taken on the same day of the event (figure 3).

2.1. Twins Days Images

These images were collected at Twins Days Festivals from 2010 to 2018 by staff from the West Virginia University – Biometrics and Identification Innovation Center. The collections were carried out under IRB protocols with informed consent from each participants. Images for each year were collected at various sizes: 2010 at 2848x4288, 2011 at 3744x5616, and 2012 to 2018 at 3300x4400 and 2400x3200. The images are all high-quality frontal portraits, conforming to NIST SAP50 specification which specifies the head and shoulders composition requirements, and SAP 51 specification which specifies the head only composition requirements [8][5].

Fig. 2. Example of twins images from University of Notre Dame Twins Days Database. (Different people)

Fig. 3. Example of twins genuine same-day images from University of Notre Dame Twins Days Database. (Same persone taken from the same.)

2.2. Immigration-related Images

All images in this set are live capture. The set is composed of mostly webcam images and some visa application images. All subjects have webcam images taken with a camera oriented by an attendant toward a cooperating subject. This is done under time constraints so there are roll, pitch and yaw angle variations. Background illumination is sometimes bright, so the face is under-exposed. There is some perspective distortion due to close range images. Some faces are partially cropped. The images are in poor conformance with the ISO/IEC 19794-5 Full Frontal image type. The images have mean interocular distance of 38 pixels. Some subjects also have visa application images that are collected in an attended interview setting using dedicated capture equipment and lighting. These visa application images have geometry in good conformance with the ISO/IEC 19794-5 Full Frontal image type, collected at size 300x300, and pose is closely frontal.

a) Application

b) Immigration Lane

Fig. 4. The figure gives simulated samples in the Immigration-related dataset.

2.3. Data Limitation and Caveats

Small population: The twins dataset is relatively small when compared to other NIST FRVT 1:1 datasets, both Twins Days data and immigration-related data combined total just over 5 900 images. During the ground-truth process, many images and twin pairs were excluded in the Twins Days data due to inconsistent or missing metadata. For example, there were mis-matched twin pairs where person A is twin to person B, but person B is twin to person C. Some images had missing or inconsistent twin type where person A is fraternal twin to person B, but person B is identical twin to person A. Other images were excluded in the Twins Days dataset that had relationship labeled as siblings, parent or child. NIST was able to keep most of the images in the immigration-related dataset, which amounted to 152 twin pairs with 2 478 images.

Different identifiers: In the Twins Days data, usually the same twins identifiers would be assigned to the same participants from year to year. However, there are cases where twins were assigned new identifiers. Therefore, a small percentage of the comparison scores were above the threshold in the non-mated non-twins comparisons leading to apparent false matches when they were actually correct matches.

Incorrect/missing Metadata: Most or all metadata was missing for Twins Days data collected in year 2011, 2014, 2015, 2016. Supplemental metadata files were later provided to NIST, but most of the information could not be match with the original data. Incorrect twin types, birthdays, and other mis-match metadata caused many images to be omitted from the study. The immigration-related images data do not have fraternal or identical twins type information, except that the images are all same sex twins. Therefore NIST cannot thoroughly analyze algorithms performance on differentiating twins by type in the operational environment.

Imbalanced Data: The overall Twins Days images distribution by twin types is uneven; 2.8% fraternal different-sex, 6.7% fraternal same-sex, and 90.5% identical twins. The

NIST IR 8439 September 2022

datasets have imbalanced age groups with most of the images in age-group 20-39. Both datasets have a very low percentage of images for the older age groups 40-59 and 60-up. The immigration-related data does not have images for age group 60-up.

Ethnicity: Twins Days data includes participants' ethnic identities, 85% of the participants identified as caucasian, 10% as African-American, and 5% as others. With the disproportionate number of ethnic groups, any analysis based on race would be meaningless.

3. Algorithms

The FRVT activity is open to participation worldwide, and the test will evaluate submissions on an ongoing basis. There is no charge to participate. The requirements to submit algorithms to NIST are described in the FRVT 1:1 Verification Application Programming Interface (API)[9] document. Participants provide their submissions in the form of libraries compiled on a specific Linux kernel, which are linked against NIST's test harness to produce executables. NIST provides a validation package to participants to ensure that NIST's execution of submitted libraries produces the expected output on NIST's test machines.

This report documents the results of algorithms submitted to FRVT 1:1 for testing from 2019 to mid-Feburary 2022, without specific claim to be able to distinguish between twins. Tables 3-13 lists the algorithms that were tested. Note that algorithms that expired or algorithms with Failed-to-enroll(FTE)=1.00 were not included in this report.

Table 13. List of algorithms included in this report.

4. Results

This section includes accuracy results for 478 one-to-one comparison algorithms submitted to FRVT during the period 2019 to mid Feburary 2022. The algorithms are listed in section 3. We do not include speed and computational resource requirements - they are given on the webpage and in Table 1 of the FRVT report. This section includes the discussion below and the results tables that follow.

Tables 14-27 show for each algorithm; its submission date, its overall false non-match rate (FNMR) on mughot images (to show capability of the algorithm), the failure-to-enroll rate (FTE) and then false match rates for the two datasets. For Twins Days images, false match rates are included for three sets of twins (identical, and same- and different-sex fraternal). For twins images collected in immigration, a single false match rate is provided for the mixed population of identical and same-sex fraternal twins. In all cases, FMR is computed as the proportion of comparisons yielding a score at or above threshold. The threshold is obtained from a set of non-twins non-mate mugshot comparisons at that value which gives a FMR of 0.0001. In those separate comparisons, mugshot FNMR is used as the control for Twins Days data, both data are full frontal image type. We adopt FNMR from comparisons of border control images² with visa like images as a control for immigration-related twins data. This allows consideration of the accuracy of algorithms. The table also includes FNMR values from mugshot and visa-border data.

The notable results are:

- ▶ **High FMR in identical twins**: In the sixth column, the identical twins FMR values are typically above 0.99 meaning almost a complete ability of a twin to be an impostor for their twin sibling. Those not above 0.99 fall into two categories: First, those³ that do not extract features from many or all images (i.e. FTE is high); and second, those⁴ that do not match any pairs (always producing low scores, so FMR is low and FNMR is high). Some of these issues arise because the algorithms do not process large images (of the size used here).
- ► Few algorithms with lower FMR on identical twins: There are some algorithms, that are generally accurate and do correctly not match some identical twins as the same person. We define these as giving FNMR ≤ 0.02, FTE ≤ 0.02, and FMR ≤ 0.7 on identical twins. These include aigen-001 and aigen-002, beyneai-000, glory-004, mobai-000, and iqface-001. The identical-twin false match rates are, at best, 0.475 for aigen-002, correctly not to match about half of identical twins as their siblings.

¹Mugshot - FRVT report-section 2.4

²Border crossing - FRVT report-section 2.3

³For example, glory-002, glory-003, id3-007, and s1-001.

⁴For example, acisw-007, facex-001, cybercore-001, csc-001, chosun-000, moredian-000, videonetics-001.

- Such FMR values are far higher than nominal (FMR = 0.0001) but somewhat below the 0.98 and 0.99 values that occur for most algorithms.
- ▶ **Algorithm-specific results**: There are individual algorithm plots of comparison score distributions by match types and age groups for both datasets (ex: Figure 1). The plots will be of primary interest to algorithm developers and end-users of those algorithms. Please refer to the algorithm report cards that are linked in the accuracy summary tables 14-27 by clicking on the algorithm name.
 - → Twins Days data similarity scores by match types: The density plot has a red vertical line at a fixed threshold. The threshold is calibrated to give FMR = 0.0001 from the FRVT 1:1 mugshot comparisons. The mugshot scores distribution in light blue represents the control scores. Algorithms with non-mated twin similarity scores to the right of threshold line authenticating the twin siblings as the same person. The threshold can be adjusted so that algorithms do not match the twin siblings; however, in a normal operational environment, it would caused the general population to fail authentication (increased false non-match error).
 - → Immigration-related data similarity scores by match types: The density plot has a red vertical line at a fixed threshold. The threshold is calibrated to give FMR = 0.0001 from the FRVT 1:1 visa-border comparisons. The visa-border scores distribution in light blue represents the control scores for immigration-related data. Similarity scores to the right of the threshold line for the same-sex twins are authenticating the twins as the same person.
 - → Twins Days data similarity scores by age groups: The plot has a red horizontal line, that is a fixed threshold calibrated to give FMR = 0.0001 from the FRVT 1:1 mugshot comparisons. Many algorithms show a decline in similarity scores in older age groups, but scores are still above the threshold to match the twins siblings as the same person.
 - → Immigration-related data similarity scores by age groups: The plot has a red horizontal line, that is a fixed threshold calibrated to give FMR = 0.0001 from the visa-border comparisons. Most algorithms don't show any decline or change in similarity scores in the older age groups.

Table 14. This table summarizes False Match Rate (FMR) on twins probe images. FMR is the proportion of twin comparisons at or above a threshold score set to achieve FMR=1e-04 on FRVT 1:1 Mugshot and Visa-Border images. FRVT 1:1 Mugshot and Visa-Border False Non-Match Rate (FNMR) is included to show the performance of the algorithms when mated comparisons are below a threshold set to achieve the same FMR=1e-04. Mugshot is used as a control for Twins Days data, and Visa-Border is used as a control for Immigration-related data

Table 15. This table summarizes False Match Rate (FMR) on twins probe images. FMR is the proportion of twin comparisons at or above a threshold score set to achieve FMR=1e-04 on FRVT 1:1 Mugshot and Visa-Border images. FRVT 1:1 Mugshot and Visa-Border False Non-Match Rate (FNMR) is included to show the performance of the algorithms when mated comparisons are below a threshold set to achieve the same FMR=1e-04. Mugshot is used as a control for Twins Days data, and Visa-Border is used as a control for Immigration-related data.

Table 16. This table summarizes False Match Rate (FMR) on twins probe images. FMR is the proportion of twin comparisons at or above a threshold score set to achieve FMR=1e-04 on FRVT 1:1 Mugshot and Visa-Border images. FRVT 1:1 Mugshot and Visa-Border False Non-Match Rate (FNMR) is included to show the performance of the algorithms when mated comparisons are below a threshold set to achieve the same FMR=1e-04. Mugshot is used as a control for Twins Days data, and Visa-Border is used as a control for Immigration-related data.

Table 19. This table summarizes False Match Rate (FMR) on twins probe images. FMR is the proportion of twin comparisons at or above a threshold score set to achieve FMR=1e-04 on FRVT 1:1 Mugshot and Visa-Border images. FRVT 1:1 Mugshot and Visa-Border False Non-Match Rate (FNMR) is included to show the performance of the algorithms when mated comparisons are below a threshold set to achieve the same FMR=1e-04. Mugshot is used as a control for Twins Days data, and Visa-Border is used as a control for Immigration-related data.

Table 22. This table summarizes False Match Rate (FMR) on twins probe images. FMR is the proportion of twin comparisons at or above a threshold score set to achieve FMR=1e-04 on FRVT 1:1 Mugshot and Visa-Border images. FRVT 1:1 Mugshot and Visa-Border False Non-Match Rate (FNMR) is included to show the performance of the algorithms when mated comparisons are below a threshold set to achieve the same FMR=1e-04. Mugshot is used as a control for Twins Days data, and Visa-Border is used as a control for Immigration-related data.

Table 24. This table summarizes False Match Rate (FMR) on twins probe images. FMR is the proportion of twin comparisons at or above a threshold score set to achieve FMR=1e-04 on FRVT 1:1 Mugshot and Visa-Border images. FRVT 1:1 Mugshot and Visa-Border False Non-Match Rate (FNMR) is included to show the performance of the algorithms when mated comparisons are below a threshold set to achieve the same FMR=1e-04. Mugshot is used as a control for Twins Days data, and Visa-Border is used as a control for Immigration-related data.

Table 27. This table summarizes False Match Rate (FMR) on twins probe images. FMR is the proportion of twin comparisons at or above a threshold score set to achieve FMR=1e-04 on FRVT 1:1 Mugshot and Visa-Border images. FRVT 1:1 Mugshot and Visa-Border False Non-Match Rate (FNMR) is included to show the performance of the algorithms when mated comparisons are below a threshold set to achieve the same FMR=1e-04. Mugshot is used as a control for Twins Days data, and Visa-Border is used as a control for Immigration-related data.
